#### Relation

In Relational Model data is modelled in form of Relations represented by tabular structure.

Consider the <u>relation</u> EMPLOYEE represented by the following table:

| Name | Desig | Grade      | JoinDate         | BasicSalary               | Gender                                | DeptCode                                     |
|------|-------|------------|------------------|---------------------------|---------------------------------------|--|
|      |       |            |                  |                           |                                       |  |
|      |       |            |                  |                           |                                       |  |
|      |       |            |                  |                           |                                       |  |
|      |       |            |                  |                           |                                       |  |
|      |       |            |                  |                           |                                       |  |
|      |       |            |                  |                           |                                       |  |
|      |       |            |                  |                           |                                       |  |
|      | Name  | Name Desig | Name Desig Grade | Name Desig Grade JoinDate | Name Desig Grade JoinDate BasicSalary | Name Desig Grade JoinDate BasicSalary Gender |

### Tuples in a Relation

A relation is a set of tuples; each row here is a <u>tuple</u>:

| EmpCode | Name | Desig | Grade | JoinDate | BasicSalary | Gender | DeptCode |   |
|---------|------|-------|-------|----------|-------------|--------|----------|---|
|         |      |       |       |          |             |        |          | 1 |
|         |      |       |       |          |             |        |          | 2 |
|         |      |       |       |          |             |        |          | 3 |
|         |      |       |       |          |             |        |          | 4 |
|         |      |       |       |          |             |        |          | 5 |
|         |      |       |       |          |             |        |          | 6 |
|         |      |       |       |          |             |        |          | 7 |

## Cardinality of a Relation

No of Tuples in a Relation at a point in time.

<u>Cardinality</u> = 7

| EmpCode | Name | Desig | Grade | JoinDate | BasicSalary | Gender | DeptCode |   |
|---------|------|-------|-------|----------|-------------|--------|----------|---|
|         |      |       |       |          |             |        |          | 1 |
|         |      |       |       |          |             |        |          | 2 |
|         |      |       |       |          |             |        |          | 3 |
|         |      |       |       |          |             |        |          | 4 |
|         |      |       |       |          |             |        |          | 5 |
|         |      |       |       |          |             |        |          | 6 |
|         |      |       |       |          |             |        |          | 7 |

#### Attribute in a Relation

An <u>attribute</u> represents a quality/information about an entity.

A tuple consists of Attribute values.

| EmpCode | Name | Desig | Grade | JoinDate | BasicSalary | Gender | DeptCode |
|---------|------|-------|-------|----------|-------------|--------|----------|
|         |      |       |       |          |             |        |          |
|         |      |       |       |          |             |        |          |

## Degree (=Arity) of a Relation

A degree or arity of a Relation is the number of attributes in it.

Degree = 8

| EmpCode | Name | Desig | Grade | JoinDate | BasicSalary | Gender | DeptCode |
|---------|------|-------|-------|----------|-------------|--------|----------|
|         |      |       |       |          |             |        |          |
|         |      |       |       |          |             |        |          |

#### Domains

Each attribute has a domain associated with it.

Attribute values in a relation are restricted to the values from its domain.

| EmpCode | Name  | Desig | Grade | JoinDate | BasicSalary | Gender | DeptCode |
|---------|-------|-------|-------|----------|-------------|--------|----------|
|         |       |       |       |          |             |        |          |
|         |       |       |       |          |             |        |          |
|         | DESIG | PE    |       |          |             | DEP    | T ACCO   |
|         |       | ТО    |       |          |             |        | PURC     |
|         |       | STO   |       |          |             |        | COUR     |

#### Consider the Employee relation defined as:

```
create table EMPLOYEE(
    EmpCode
                integer(4),
                char(30),
    Name
    Desig
                char(4),
                integer(4),
    Grade
    JoinDate
                date,
                integer(7),
    Basic
    Gender
                char(1),
                char(4)
    DeptCode
```

#### Domains of Attributes: Example

```
EmpCode
          set of all 4-digit numbers
          set of all 30-alpha characters
Name
          set of all designation codes
Desig
Grade
          set of all grade values
          set of all dates (in a given range)
JoinDate
          set of all possible values for basic
Basic
          set {'M','F', 'T'}
Gender
DeptCode
          set of all dept codes
```

# A Relation may be represented as a Table where

| Relation     | Table                                  |
|--------------|--|
| Tuple        | Row/Record                             |
| Attribute    | Column                                 |
| Degree/Arity | No of Columns in the table             |
| Cardinality  | No or Rows in the table                |
| Domain       | Pool of acceptable values for a column |
| Primary Key  | Unique Identifier                      |

#### But, a Relation is not a Table, because:

- A table has an inherent order for rows; there is no concept of order for tuples in a relation.
- A relation must have a <u>Primary Key</u>; a table need not have an identifier/Primary Key.
- The tuples in a relation must be unique; there is no such restriction for tables

#### Relation: Observations

- A Relation is a set of tuples.
- A Relation is time-variant.
- A Relation cannot have duplicate tuples.
- Tuples in a Relation are unordered.
- Values are Atomic.
- Values for a single attribute are of same kind.
- A Relation is a subset of the <u>Cartesian Product</u> of a set of domains.

## Candidate Key & Super Key

A **Candidate Key** must satisfy following time-independent properties:

- <u>Uniqueness property</u>: No two distinct tuples have the same value for the key.
- Minimality property: None of the attributes of the key can be discarded from the key without destroying the uniqueness property.

A <u>Super Key</u> is a Non-Minimal Candidate Key. Its a set of one or more columns in a table for which no two rows can have the exact same values.

An Alternate Key is a candidate key that is not the primary key.

### Candidate Key?

```
create table EMPLOYEE(
     EmpCode
                 integer(4),
     Name
                 char(30),
     Desig
                 char(4),
                 integer(4),
     Grade
     JoinDate
                 date,
                 integer(7),
     Basic
                 char(1),
     Gender
                 char(4)
     DeptCode
```

#### Candidate Key?

```
create table EMPLOYEE (
     EmpCode
                 integer(4),
                 char(30),
     Name
     Desig
                 char(4),
                 integer(4),
     Grade
                 date,
     JoinDate
                 integer(7),
     Basic
                 char(1),
     Gender
     DeptCode
                 char(4),
                 char(100),
     Email
     MobileNo
                 char(16)
```

## Primary Key

Is a candidate key that have following two qualities -

- Uniquely identifies a tuple in a relation
- Must NOT be NULL

\*Should be selected from candidate keys such that it never/rarely changes.

## Primary Key?

```
create table EMPLOYEE (
     EmpCode
                 integer(4),
                 char(30),
     Name
     Desig
                 char(4),
     Grade
                 integer(4),
                 date,
     JoinDate
                 integer(7),
     Basic
                 char(1),
     Gender
     DeptCode
                 char(4),
                 char(100),
     Email
                 char(16)
     MobileNo
```

### Composite Key

- A candidate key with two or more attributes that uniquely identifies the tuple in a Relation.
- Also called as <u>compound key</u>

#### **Composite Primary Key**

• A primary key which is a composite key is called as Composite Primary Key.

# Can we have more than one primary key in a table?

No. We can not.

DO NOT get confused with the restriction of single Primary Key in a table and the concept of Composite Key. To clarify the same -

#### A table can have only one Primary Key.

The Primary Key can be defined on a single column or more than one columns. If the Primary Key is defined using more than one columns, it is known as a Composite Key (or Composite Primary Key).

Therefore, a Composite Key in a table does not mean that there are more than one Primary Keys in the table. Instead, a Composite Key uses more than one columns to define a (Single) Primary Key.

## Foreign Key

- A <u>Foreign Key</u> is a set of attributes in one relation whose values are required to match one of the values of the primary key of the <u>same or different relation</u>.
- There can be more than one foreign key in a given relation.

Identify a relation in any system/business, define its Attributes, Domain for each attribute and find out Primary, Key, Foreign Keys, Candidate Keys, Super Key in the relation.

## Foreign Key(s)?

```
create table EMPLOYEE(
     EmpCode
                  integer(4),
                  char(30),
     Name
                  char(4),
     Desig
     Grade
                  integer(4),
     JoinDate
                  date,
                  integer(7)),
     Basic
     Gender
                  char(1),
                  char(4)
     DeptCode
create table DEPT(
     <u>DeptCode</u>
                  char(4),
                  char(30),
     DeptName
     Location
                  char(10)
```

## Integrity Rules

#### **Entity Integrity**: Implemented through Primary Key

"No Attribute participating in the primary key of a relation may accept null values"

Guarantees that each tuple will have a unique identity.

**Referential Integrity**: Implemented through Foreign Key

"Values of the foreign key (a) must be either null, or (b) if non-null, must match with the primary key value of some tuple of the `parent' relation. The reference can be to the same relation"

\*Foreign Key is also know as Reference/Referential key.

## Relational Database Operations

• **SELECTION** ( $\sigma$ ) : Selects some or all of the records in a table.

Through WHERE Clause

• **PROJECTION**( $\pi$ ) : Limits columns from a table.

Through SELECT Clause

- UNION / INTERSECTION / DIFFERENCE (MINUS)
- JOIN
- CARTESIAN PRODUCT
